

Mapping Ecosystem Connectivity

Diamond Head Consulting
Aubrey Butcher

An Ecological Network

- Urbanization and industry has historically focused on lowland/waterfront and resource rich areas which support high levels of biodiversity
- As cities develop, these valuable habitats are lost and become fragmented

1895 – North Arm Road, Granville

An Ecological Network

- Connectivity is critical for wildlife to access habitat
- Allows for populations to interbreed
- Isolation of populations can impact genetics
- Prey and predator dynamics become unbalanced
- Constraining wildlife movement can increase predation

An Ecological Network - Goals

- Maximizes the value of natural areas and their ability to support as many species as possible with a focus on species that are at risk.
- Protects and connects the most valuable habitat
- Prioritises habitat resources for protection and restoration

An Ecological Network

Biodiversity of a natural area depends on:

- Its size - smaller patches of natural areas have lower biodiversity
- The amount of habitat edges
- How species move
- Their tolerance for and ability to move through urban areas

Who are we managing for?

Urban Adaptors and Exploiters

- Species that can thrive in urbanized context
- Adapted their natural needs
- Use available urban resources, reproduce rapidly, and avoid predation
- Includes non native invasive species

Urban Tolerators

- Require patches of natural plant communities, protection from predators, or food sources that are rarely found in urban contexts.
- Tend to live on the fringes of urban environments

Who are we managing for?

Urban Avoiders

- Low tolerance for urban environments.
- Elusive and have highly specific habitat requirements not common in Cities
- Rare in urban settings
- Many are species at risk

Biodiversity Ranking

Biodiversity Ranking

Components of an EN

- Habitat Hubs
- Habitat Sites
- Movement Corridors

Components of an EN

Core habitat refuge areas

- Large in size (typically >10 ha)
- Provide protected interior habitat
- Refuge areas for wildlife

Stepping stone habitat

- Smaller patches (typically <10 ha)
- More interface edges
- Little refuge areas for wildlife

Components of an EN

Regional wildlife corridors

- Linear natural habitat
- Connect habitat patches together
- Wide and continuous

Local wildlife corridors

- Narrow and fragmented by urban barriers
- 10-30 m wide
- Provide natural cover for birds, flying insects and mammals tolerant of urban activity

Components of an EN

Greenway corridors

- Multi-use linear pathway network
- narrower with fragmented, inconsistent natural features
- can be improved by planting trees, hedgerows, and pollinator-friendly flowers
- Support urban tolerant wildlife

Aerial corridors

- No easy terrestrial movement
- Connected tree canopies supporting aerial movement through urban landscapes
- Supports flying insect and birds as well as highly tolerant terrestrial wildlife

Components of an EN

The Urban Matrix

- Natural areas intermixed within an urbanized landscape
- Small patches of habitat
- Single or small groups of trees
- Non-native habitat features such as garden areas
- Habitat for mostly flying and urban tolerant wildlife
- Enhanced engineered assets (e.g. rain gardens, bioswales, green roofs, green walls)

Examples of ENs

There are a wide variety of examples which vary in

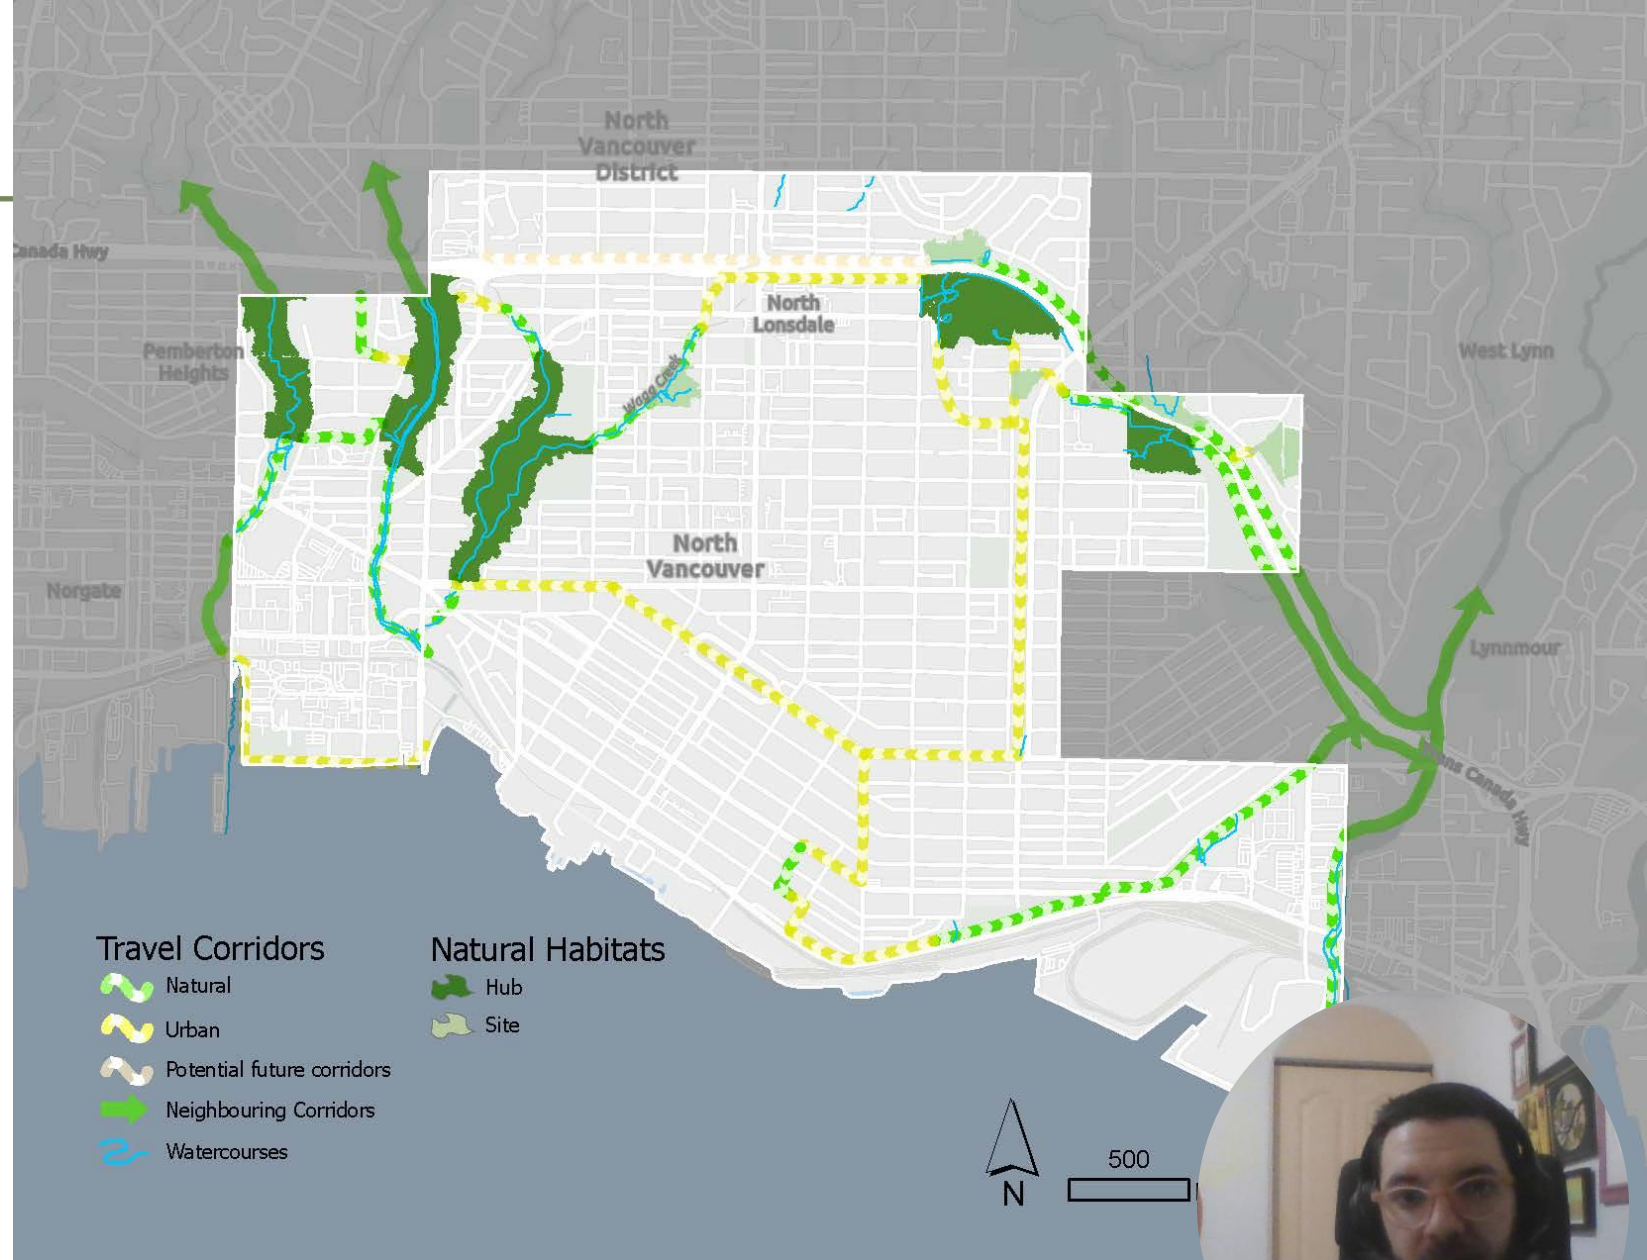

- Scale
- Components
- Terminology

Metro RGIN - Methodology

Automated GIS steps

- Step 1 – Identify the Core Terrestrial Habitat Areas to include in this analysis
- Step 2 – Use the Ecosystem Connectivity Analysis to evaluate these habitat areas for their connectivity importance
- Step 3 – Identify least-cost path travel corridors between this habitat areas

Draft methodology and testing

Step 1 - Identify Core Terrestrial Habitat Areas

- These will be considered when identifying and prioritising a network
- SEI ecosystems - old, mature and young forest, alpine, estuarine, freshwater, herbaceous, old field, riparian, sparsely vegetated, woodland, and wetland.
- Add all land cover classes for terrestrial habitat that are adjacent/contiguous or within 30m from the SEI polygons and are greater than 0.5 hectares in size.

Metro Vancouver 2020 Sensitive Ecosystem Inventory and Land C

Draft methodology and testing

Step 2 – Analyze patches to determine which are most important

- Overlay core patches with connectivity metrics to determine patch importance for connectivity

Draft methodology and testing

Step 3 – Identify important corridors that connect core habitat areas

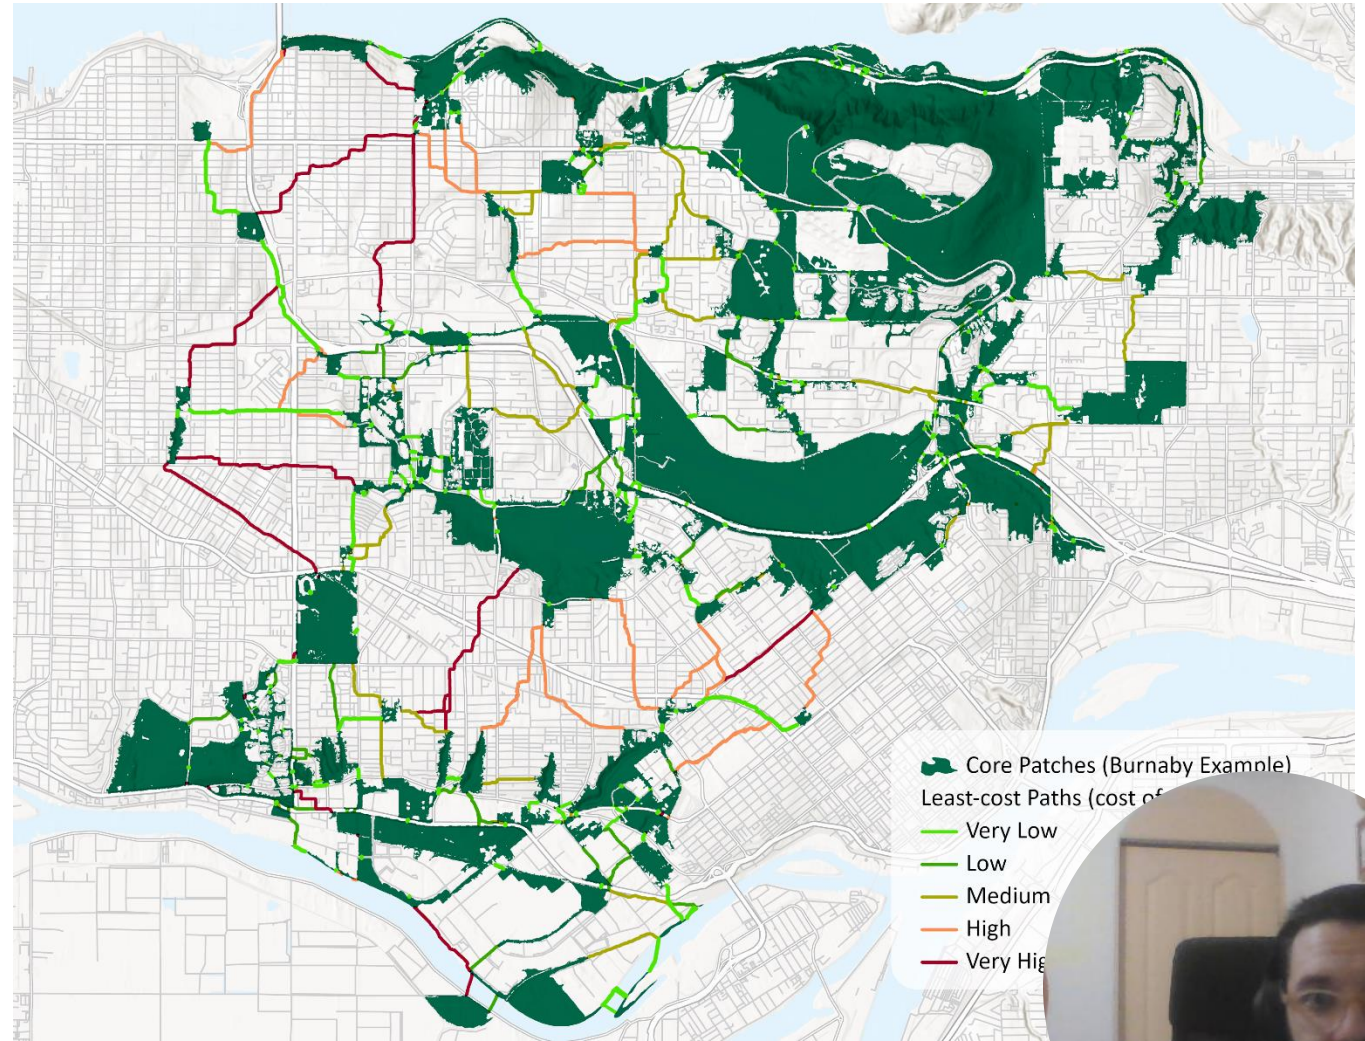

- Use the analysis tool “Optimal Region Connections” to identify least-cost paths connecting the core terrestrial habitat areas
- Uses a cost of movement raster based on land cover data
- Analyse excludes patches that have a low connectivity score

Draft methodology and testing

Step 3 – Identify important corridors that connect core habitat areas

Computer generated cost of movement corridors

Computer generated cost of movement between habitat areas

- | | |
|---------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| Cost of Movement |  Lakes and Ponds |
|  Very Low |  Natural Streams |
|  Low |  Restored Streams |
|  Medium |  Ditches |
|  High |  Core Habitat Refuge Areas |
|  Very High |  Stepping Stone Habitat |
| |  Urban Matrix |

Cost of movement indicates the difficulty of moving for species across the landscape. This does not indicate the cost of land acquisition.

A low-angle photograph of a forest with tall trees and sunlight filtering through the canopy. The sun is visible in the center, creating a bright lens flare. The trees are tall and thin, with green foliage. The sky is visible through the branches.

Thank you!
